## Federal Aviation Administration, DOT

| Number of pas-<br>senger seats | Minimum main passenger aisle width |                               |  |
|--------------------------------|------------------------------------|-------------------------------|--|
|                                | Less than 25 inches from floor     | 25 inches and more from floor |  |
| 10 through 19                  | 9 inches                           | 15 inches.                    |  |

(b) When certification to the emergency exist provisions of §23.807(d)(4) is requested, the main passenger aisle width at any point between the seats must equal or exceed the following values:

|                           | Minimum main passenger aisle width (inches) |                                     |  |
|---------------------------|---------------------------------------------|-------------------------------------|--|
| Number of passenger seats | Less than<br>25 inches<br>from floor        | 25 inches<br>and more<br>from floor |  |
| 10 or fewer               | <sup>1</sup> 12<br>12                       | 15<br>20                            |  |

<sup>&</sup>lt;sup>1</sup> A narrower width not less than 9 inches may be approved when substantiated by tests found necessary by the Administrator.

[Amdt. 23–34, 52 FR 1831, Jan. 15, 1987, as amended by Amdt. 23–46, 59 FR 25774, May 17, 1994]

## §23.831 Ventilation.

- (a) Each passenger and crew compartment must be suitably ventilated. Carbon monoxide concentration may not exceed one part in 20,000 parts of air.
- (b) For pressurized airplanes, the ventilating air in the flightcrew and passenger compartments must be free of harmful or hazardous concentrations of gases and vapors in normal operations and in the event of reasonably probable failures or malfunctioning of the ventilating, heating, pressurization, or other systems and equipment. If accumulation of hazardous quantities of smoke in the cockpit area is reasonably probable, smoke evacuation must be readily accomplished starting with full pressurization and without depressurizing beyond safe limits.
- (c) For jet pressurized airplanes that operate at altitudes above 41,000 feet, under normal operating conditions and in the event of any probable failure conditions of any system which would adversely affect the ventilating air, the ventilation system must provide reasonable passenger comfort. The ventilation system must also provide a sufficient amount of uncontaminated air to enable the flight crew members to perform their duties without undue discomfort or fatigue. For normal oper-

ating conditions, the ventilation system must be designed to provide each occupant with at least 0.55 pounds of fresh air per minute. In the event of the loss of one source of fresh air, the supply of fresh airflow may not be less than 0.4 pounds per minute for any period exceeding five minutes.

(d) For jet pressurized airplanes that operate at altitudes above 41,000 feet, other probable and improbable Environmental Control System failure conditions that adversely affect the passenger and flight crew compartment environmental conditions may not affect flight crew performance so as to result in a hazardous condition, and no occupant shall sustain permanent physiological harm.

[Doc. No. 4080, 29 FR 17955, Dec. 18, 1964; 30 FR 258, Jan. 9, 1965, as amended by Amdt. 23–34, 52 FR 1831, Jan. 15, 1987; Amdt. 23–42, 56 FR 354, Jan. 3, 1991; Amdt. 23–62, 76 FR 75757, Dec. 2, 2011]

## PRESSURIZATION

## §23.841 Pressurized cabins.

- (a) If certification for operation above 25,000 feet is requested, the airplane must be able to maintain a cabin pressure altitude of not more than 15,000 feet, in the event of any probable failure condition in the pressurization system. During decompression, the cabin altitude may not exceed 15,000 feet for more than 10 seconds and 25,000 feet for any duration.
- (b) Pressurized cabins must have at least the following valves, controls, and indicators, for controlling cabin pressure:
- (1) Two pressure relief valves to automatically limit the positive pressure differential to a predetermined value at the maximum rate of flow delivered by the pressure source. The combined capacity of the relief valves must be large enough so that the failure of any one valve would not cause an appreciable rise in the pressure differential. The pressure differential is positive when the internal pressure is greater than the external.
- (2) Two reverse pressure differential relief valves (or their equivalent) to automatically prevent a negative pressure differential that would damage the structure. However, one valve is
